# Does the inverter have an AC contactor

### **Overview**

What is the difference between AC and DC contactors?

The main difference lies in how they handle the arc that is generated when the contacts open and close. AC contactors use the zero-crossing of the AC waveform to help extinguish the arc, while DC contactors require additional arc suppression mechanisms.

What happens if an inverter/charger has a small resistance difference?

Each inverter/charger contains an internal AC input contactor. These contactors are not always completely identical, they can have a small difference in their internal resistance, compared to the other contactors. This small resistance difference might result in the AC current being diverted from one unit to another.

What are the different types of AC contactors?

AC contactors are mostly available in 3-pole and 4-pole versions. You can choose between them depending on the load type and control circuit requirements. For instance, 3-pole AC contactors are usable in three-phase systems, while 4-pole AC contactors can be used in 3 phase 4 wire system or 1 phase 2 wire system.

How does AC contactor work?

The working principle of the AC contactor involves electromagnetic force cooperating with the spring force to make and break the connection between the source and load. Basically, when the coil is energized with a low voltage, it generates a magnetic field and attracts the armature.

What is an example of the internal wiring of an inverter/charger?

Example of the internal wiring of an inverter/charger. In a parallel system, the AC current should be evenly distributed through all paralleled inverter/charger units. When the resistance in the cabling is very low, the small difference in

contactor resistance will result in a large relative difference.

What components make an AC contactor?

The components that make an AC contactor are: Coil - The electromagnetic coil is the heart of the contactor. It creates a magnetic field that pulls the contacts together to close the circuit when energised. This coil is usually made of copper or aluminium wire. It is wound tightly to generate sufficient magnetic force.
