# **Energy Storage Load Following System**

#### **Overview**

What is a grid following energy storage system?

Grid following energy storage systems, also known as grid-tied or griddependent systems, are designed to sync with the existing power grid. These systems rely on the grid to maintain frequency and voltage stability. Essentially, they "follow" the grid's lead.

What is load following?

Load following is an operating strategy in which generators change their output to match changes in electric demand, or load. Batteries are used for load following because their output can be digitally controlled and therefore can respond to load changes with less stress than mechanical systems.

Why are batteries used for load following?

Batteries are used for load following because their output can be digitally controlled and therefore can respond to load changes with less stress than mechanical systems. Nearly 400 MW of battery storage capacity was used for load following in 2020.

How do you quantify the energy storage potential of load control?

To continue the energy storage device analogy discussed in the introduction, one can quantify the storage potential of this type of load control by computing the maximum cumulative energy consumed before or after it would have been in steady state conditions.

Can thermostatically controlled loads serve as virtual storage devices?

This paper demonstrates that populations of thermostatically controlled loads can be collectively managed to serve as virtual storage devices that follow variability in generation from renewable electricity generators (or in demand from other loads).

Can TCLs deliver services on both regulation and Load scales?

The simulation results here indicate that TCLs can be used to deliver services on both the regulation and load following time scales, and that each controlled load provides the equivalent of a storage device with 0.5 kWh of energy capacity and 0.75 kW of power capacity.
